The Morphometric Analysis of the Mental Foramen in Adult Dry Human Mandibles: A Study on the South Indian Population

K. UDHAYA¹, K.V. SARALADEVI², J. SRIDHAR²

ABSTRACT

Aim: The mental foramen is a small foramen which is located in the antero-lateral aspect of the body of the mandible. It is situated midway between the upper and the lower border of the mandible and it transmits the mental nerve and the vessels. The knowledge on the anatomy of the mental foramen is very important in clinical dentistry and in surgical procedures which involve that area.

Material and Methods: Our study was conducted on 90 adult dry human mandibles from the South Indian population, irrespective of age and sex. The location, shape, orientation and the presence of the accessory foramen were studied by visual examination. The size and position of the mental foramen were measured by using a digital vernier caliper. The SPSS, version 15 software was used for the statistical analysis, to calculate the minimum, maximum, incidence, mean and standard deviation.

Results: In a majority of the mandibles, the mental foramen was located at the level of the root of the 2nd premolar, midway between the inferior margin and the alveolar margin of the mandible. Most of the mental foramina were oval in shape. The orientation of the foramen was postero-superior in 83% of the mandibles. The accessory foramens were noted in five mandibles.

Conclusion: The knowledge on the variations in the position and size of the mental foramen and the presence of the accessory foramen may be of much use to dental surgeons.

INTRODUCTION

The Mental Foramen (MF) is located in the body of the mandible, midway between the inferior and the alveolar margins of the body [1,2]. It is present between the premolars, in a vertical line with the supraorbital notch. It provides a passage for the exit of the mental nerve and the vessels [3]. Most of the mental foramina are oriented postero-superiorly.

Variations in the position of the MF have been reported by many authors in different ethnic groups [4,5] and various shapes have also been noticed [6]. Any foramen which is in addition to MF is considered as an Accessory Mental Foramen (AMF) and it is usually located below the 1st molar teeth [8]. This accessory mental foramen may transmit the branches of the mental nerve.

The precise knowledge on the variations in the position, shape, and the size of the mental foramen would be of much use for dental surgeons while they do surgical procedures on the mandible, such as the Curettage of the premolars, Filling procedures, Dental implants, Root Canal Treatments (RCT), Orthognathic surgeries, etc. It is also essential to have an effective and a successful anaesthesia during nerve blocks, prior to the surgical procedure. Many studies have been reported by various authors, which were done in different ethnic groups and on populations of different races, but such studies which have been reported in the South Indian population are sparse. Hence, an attempt was made in our present study, to determine the most common position and size of the mental foramen in adult South Indian mandibles, which may be useful for the future implications in our South Indian population.

MATERIAL AND METHODS

The mandibles which were used for our study were procured from the Department of Anatomy, Vinayaka Mission Kirupananda Variyar Medical College and from Annapoorna Medical College, Salem, Tamil Nadu, India. About 90 adult dry South Indian mandibles, irrespective of age and sex, with either all the teeth intact or with preserved alveolar margins, were used for our study. The bones with gross pathological deformities were excluded from our study.

The number, shape and the orientation of the MF were determined by a visual examination.

The positions of the mental foramens were measured with respect to the teeth, for which we followed the Tebo and Telford [9] classification [Table/Fig-1]. The positions of the mental foramens with respect to the borders were also measured [Table/Fig-2] with the help of a digital vernier caliper, at a measuring accuracy of 0.01mm. From the transverse and the vertical diameters which were obtained, the size of the MF was calculated.

The transverse diameters were measured by using various parameters viz., the distance from the symphysis menti, the posterior border of the mandible, the base of the mandible and from the alveolar margins.

AD – The distance from the symphysis menti to the posterior border of the mandible.
AB – The distance from the symphysis menti to the anterior margin of the MF
CD – The distance from the posterior margin of the MF to the posterior border of the mandible.
BC – The transverse diameter (TD) of the MF
The vertical diameters were measured by using the following parameters viz.,
PS – The distance from the alveolar margin to the base of the mandible
PQ – The distance from the alveolar margin to the superior margin of the MF
RS – The distance from the inferior margin of the MF to the base of the mandible.
QR – The vertical diameter (VD) of the MF

All the measurements were recorded by one of the authors to reduce bias. The SPSS, version 15 version software were used for the statistical analysis, to find out the minimum and the maximum

Key words: Mental foramen, Mandible, South Indian
incidences, the mean and the standard deviation.
For the accessory mental foramen, the number, location, shape, size and the orientation were recorded [Tables/Fig-3 and 4].

RESULTS
The Mental Foramen

Number
In our present study, 87 bones (96.67%) showed a single mental foramen on the left side and 88 (97.78%) showed a single foramen

Position
The position of the MF with respect to the teeth of the lower jaw were classified according to the method of Tebo and Telford, 1950.
I. The foramen which lay on a longitudinal axis which passed between the canine and the first premolar.

II. The foramen which lay on the longitudinal axis of the first premolar.

III. The foramen which lay on the longitudinal axis which passed between the first and second premolars.

IV. The foramen which lay on the longitudinal axis of the second premolar.

V. The foramen which lay on the longitudinal axis which passed between the second premolar and the first molar.

VI. The foramen which lay on the longitudinal axis of the first molar.

As per this classification, the analysis showed that the most common position in our study was the longitudinal axis of the 2nd premolar (IV), followed by (V) i.e between the 2nd premolar and the first molar, between the 1st and 2nd premolars (III) and the axis of the premolar (II) [Table/Fig-5] respectively. Position I and VI were not observed in any of the mandibles. With respect to the superior and the inferior borders of the mandible, most of the MF (85.56% on the left side and 86.67% on the right side) were found to occupy the mid position [Table/Fig-6].

The MF was positioned at an average distance of 12.21 ± 2.61 mm from the alveolar margin on the left side, whereas it was positioned at a distance of 12.02 ± 2.48 mm on the right side. From the symphysis menti, the MF was located at a distance of about 25.29 ± 2.29 mm on the left side and at a distance of about 25.79 ± 1.78mm on the right side. The average distance of the MF from the posterior border of the mandible was 63.92 ± 4.26 mm on the left
In 75 bones, (83.33%) the MF was bilaterally showing an oval shape and in the remaining 15 mandibles (16.67%) the MF was bilaterally showing a round shape [Table/Fig-7]. Most of the MFs (83%) on the left side and 80% on the right side were oriented postero-superiorly and this was followed by a superior and then a horizontal orientation [Table/Fig-9].

The Accessory Mental Foramen (AMF)

The incidence of the AMF was more (3.33%) on the left side as compared to that on the right side (2.22%). One mandible out of 90 showed AMF bilaterally. The total incidence of AMF was 5.55% [Table/Fig-10].

**DISCUSSION**

Our study demonstrated that the most common position of the MF, was position IV, followed by position V, which was similar to that of North Americans [9], North Indians [10], Turks [11], Malawians [12] and Zimbabweans [13] [Table/Fig-11]. Our study findings coincided with those of Agarwal and Gupta [6] and Yesilyurt et al., [14] in different populations. This finding differed significantly from the finding of Gershenson et al., [15] who reported a higher prevalence of the positions I, II and VI between the Indians and the Sinai population. Also, the studies which were done on Nigerians [16] and Kenyans [17] showed the most common position to be III, followed by II. In Malays and in the Srilankan population, it was noticed that position IV was followed by position III [18,19]. Hence, significant differences have been reported in the positions of the MF among different ethnic groups [Table/Fig-11]. Sometimes, an anterior loop of the mental nerve may be present medial to the MF and it may cause a mental nerve injury during a dental implantation [20].

Chung et al., [21] reported that the Horizontal Diameter (HD) of the MF was 2.4 mm, whereas Apinhasmit et al., reported a diameter
products of the genetically determined growth processes of other tissues, which had affected the bone formation. Subsequently, they undergo modifications during ontogeny and variable degrees of expression. Thus, the variations in the position, shape, number and size of the MF depends on the gene modification.

The Accessory Mental Foramen

In our study, 3.33% of the mandible showed AMFs on the left side and 2.22% showed AMFs on the right side. Our results were in contrast with those of Singh and Srivastava [10], where they found 8% AMFs on the left side and 5% on the right side. The incidence of the AMF in the Israeli population [15] was 2.8%, it was 1.8% among the American whites, it was 12.5% among Polynesians. Cag Irankaya and Kansu [8], Singh et al., [10] recorded AMFs below the 1st molar. But in our study, each AMF showed a variable position viz., between the 2nd premolar and the 1st molar, followed by between the 1st molar and the 2nd premolar (left side); between the 2nd premolar and the 1st molar and then between the 1st premolar and the 2nd premolar (right side). The literature on this are very sparse in Indian studies.

The literature on the size of the AMF is hardly available, to compare with ours. Singh et al., [10] recorded an average diameter of 1mm, but our study recorded a vertical diameter of 2.22 mm with an HD of 1.58 mm on the left side. Similarly, a VD of 1.76 mm and an HD of 3.9 mm on the right side were recorded.

CONCLUSION

The knowledge on the variations of the mental foramen is important for dental surgeons while they perform endodontic and periodontal surgeries, dental implantations, orthognatic surgeries, etc. Also, the verification on the presence of the AMF would prevent an accessory mental nerve injury during surgery and inadequate paraesthesia. Our present study on the variations in the position, size, shape and the existence of the AMF would be of use, for preventing complications and for better outcomes of the surgical procedures which are related to the mental foramen and the mental nerve.
